6 **6.36 Returning Error Status [NZN]**

7

8 **6.36.1 Description of application vulnerability**

9

10 Programming languages provide multiple mechanisms for the reporting of errors. Whether

11 these errors are programmatic or generated by the operating environment, improper or

12 ineffective error returning can mask other vulnerabilities, and corrupt data and process flow.

13

14 **6.36.2 Cross reference**

15

16 **6.36.3 Mechanism of failure**

17

18 Some languages provide mechanisms to return error by raising exceptions, creating and raising

19 error objects, or setting of environmental variables of semaphores. If none of these

20 mechanisms exist, the subroutines can return error status, or set global variables to indicate

21 that an error occurred. Failure mechanisms include:

- 22
- 23 • not properly transmitting error conditions to the calling routines
 - 24 • ignoring error conditions that occur
 - 25 • improperly documenting error return code or variables
 - 26 • not providing enough status information to determine the nature of the error

27

28 **6.36.4 Applicable language characteristics**

29

30 This vulnerability is endemic to all languages, to one extent or another. Those languages that do not

31 provide a language defined method of returning errors are more vulnerable to improper documentation

32 and insufficient status information.

33

34 **6.36.5 Avoiding the vulnerability or mitigating its effects**

35

36 Software developers can avoid the vulnerability or mitigate its ill effects in the following ways:

37

- 38 • Always return status, in some form or another
- 39 • Always check status from any subroutine or subprogram
- 40 • When creating error statuses, be consistent throughout the project, and provide enough detail
- 41 to determine what caused the error
- 42 • When a language provided error mechanism does not allow the granularity or environmental
- 43 detail to properly debug the error, create global or status arrays to return that data

44

45 **6.36.6 Implications for standardization**

46

47 In future standardization activities, the following items should be considered:

48

- 49 • Providing language features to return error status
- 50 • Providing language features that allow extended environmental data that is relevant to the

51 error, such as data in error, data base record number, data items that may be affected, etc.

52

53 **6.nn Exception Conditions**

54

55 **6.nn.1 Description of application vulnerability [???**

56

57 Most software environments provide a method for detecting conditions that do not correspond to those
58 expected. These may be environment related, such as hardware failures, or unexpected communication
59 results, data related, such as a non-numeric item input to a numeric calculation, or software related,
60 such as unexpected numeric overflows, or improper index calculations. Many other vulnerabilities are
61 detectable within the software environment. Ignoring this detection, or providing a generic error
62 handling routine may lead to corrupt code, and may provide a vehicle for malicious attack.

63

64 **6.nn.2 Cross reference**

65

66 **6.nn.3 Mechanism of failure**

67

68 Exception conditions can provoke failure in a number of ways:

69

- 70 • Unhandled exceptions may end up being ignored, thereby corrupting data or process
- 71 flow.
- 72 • Unhandled exceptions may be considered fatal by the operating environment, thereby
- 73 terminating execution without finalizing the process, leaving open or corrupt databases,
- 74 other processes blocked while waiting for results, or resources left in a locked state.
- 75 • Generically handled exceptions may not capture appropriate environmental and
- 76 program state to allow the error to be properly investigated
- 77 • Generically handled exceptions may not free local resources properly

- 78
- Generically handled exceptions may not be able to correct a specific correctable error and return to processing
- 79
- Some error handling mechanisms may allow inappropriate returns from an error handling routine.
- 80
- 81

82

83 **6.nn.4 Applicable language characteristics**

84

85 Different programming languages handle error conditions in a number of manners. The main error
86 handling methodologies are:

87

- Try-Catch uses a block structure to "catch" errors that occur with the block.
 - Error-Condition sets a predefined error condition code that can be checked with a conditional expression
 - Error-Status sets a user defined variable to a predefined code that specifies the error
 - Error-Object creates an object that defines the error, along with environmental conditions
 - Declaratives are routines that will be executed when particular error conditions occur.
- 88
- 89
- 90
- 91
- 92
- 93
- 94

95 **6.nn.5 Avoiding the vulnerability or mitigating its effects**

96

97 Software developers can avoid the vulnerability or mitigate its ill effects in the following ways:

98

- Check error status and error conditions when possible.
 - Check errors with the smallest possible granularity. Whenever possible keep the block that is tested to the smallest number of operations.
 - Always close and release any open resources during error processing when the error is uncorrectable
 - When an error is uncorrectable, propagate the error upwards when possible, after cleaning up open resources.
 - Never disable error handling without extreme provocation.
 - When multiple error handling methodologies are provided, try to standardize on a single methodology for the project.
- 99
- 100
- 101
- 102
- 103
- 104
- 105
- 106
- 107
- 108
- 109

110 **6.nn.6 Implications for standardization**

111 In future standardization activities, the following items should be considered:

- A standardized set of mechanisms for detecting and treating error conditions should be developed so that all languages to the extent possible could use them. This does not mean that all languages should use the same mechanisms as there should be a variety, but each of the mechanisms should be standardized.
- 112
- 113
- 114
- 115

116
